1.0 INTRODUCTION

The work reported herein was jointly sponsored by and conducted for the Arnold Engineering Development Center (AEDC)/DO and the Johnson Space Center, NASA/JSC, Houston, Texas. The work was done at the Arnold Engineering Development Center, Air Force Systems Command (AFSC), Arnold Air Force Station, Tennessee by ARO, Inc., AEDC Division (a Sverdrup Corporation Company), contract operator of the AEDC. The test was conducted in the Propulsion Wind Tunnel Facility (PWT), Propulsion Wind Tunnel, Transonic (16T) during the periods September 19 and 20, 1978 and September 29 and 30, 1978 under ARO Project Number P41T-35.

The objectives of the test were (1) to adequately define test section flow angularity for a 0.03-scale model of the NASA Space Shuttle Launch Vehicle in both the pitch and sideslip planes at Mach numbers from 0.60 to 1.55, and (2) to provide a data base throughout an α/β matrix for the determination of flow angularity corrections to be applied to previously obtained data if such corrections are necessary.

The final data from the test have been transmitted to Johnson Space Center, Houston, Texas. Requests for these data should be directed to Johnson Space Center, EX 33, Houston, Texas 77058. A copy of the final data is on file on microfilm at AEDC.

2.0 APPARATUS

2.1 TEST FACILITY

The AEDC Propulsion Wind Tunnel (16T) is a variable density, continuous-flow tunnel capable of being operated at Mach numbers from 0.2 to 1.6 and stagnation pressures from 120 to 4000 psfa. The maximum attainable Mach number can vary slightly depending upon the tunnel pressure ratio requirements with a particular test installation. The maximum stagnation pressure attainable is a function of Mach number and available electrical power. The tunnel stagnation temperature can be varied from about 80 to 160°F depending upon the available cooling water temperature. The test section is 16 ft square by 40 ft long and is enclosed by 60-deg inclined-hole perforated walls of six-percent porosity. The general arrangement of the test section with the test article installed is shown in Fig. 1. Additional information about the tunnel, its capabilities and operating characteristics is presented in Ref. 1.

2.2 TEST ARTICLES

The test article was a scaled replica of the Rockwell International Space Shuttle Vehicle in its launch configuration. The launch configuration consisted of the orbiter, an expendable external oxygen/hydrogen fuel tank (ET), and two expendable Solid Rocket Boosters (SRB's).

The orbiter has a blended wing body with a double delta planform (81 deg/45 deg) with full span elevons. The single, 45-deg swept vertical stabilizer had rudder deflection capability but was maintained at 0 deg throughout the tests. The single, aft body flap was present but was not deflected during the tests.

The external fuel tank was cylindrical in cross section having a tangent ogive forebody terminating in a biconic nose cap. The aft end of the ET was basically an ellipsoid of revolution.

The Solid Rocket Boosters (SRB) were attached to the ET by forward and aft attach lugs and were in the centerline horizontal plane of the ET. The SRB's were cylindrical in cross section and had an 18-deg semi-angle forebody which terminated in a spherical tip.

Dimensions of the primary model components are given in Fig. 2 and more detailed descriptions and drawings of the model may be found in Ref. 2.

2.3 SUPPORT SYSTEMS

The Tunnel 16T standard sting support system which is shown in Fig. 1a and described in Ref. 1 was used to support and position the model in the test section during the first test entry. The model was supported by a dual sting arrangement consisting of two 2.0-in.-diam stings exiting from the bases of the left and right hand solid rocket boosters (SRB). These stings were then attached by adapters to 4.16-in.-diam parallel stings which were mounted into the sting support system. This support arrangement allowed the base of the orbiter to be essentially free from any support system interference (see Fig. 3). The sting support system utilizes computer control to position the model at angles of attack and sideslip through combinations of pitch and roll angles. This model support system is advantageous in that the model can be maintained at, or very close to, the tunnel centerline where flow angularity is a minimum. A photograph of the model installed on the sting support system is presented in Fig. 4.

The High-Pitch model support system was utilized for the second test entry. The High-Pitch support system was mounted into a dummy roll mechanism of the standard sting support system and utilized the vertical traverse feature of the latter system to maintain the orbiter as close to tunnel centerline as possible within the physical constraints of ± 36 in. vertical traverse of the sting support system. The geometry of the High-Pitch support and the location of the orbiter model component relative to the supporting dual stings enabled the orbiter to be maintained close to tunnel centerline at angles of attack of zero deg or greater during pitch polars conducted at zero deg roll angle. During pitch polars conducted with the model roll 180 deg, the orbiter model component was below centerline at all angles of attack and its location relative to the tunnel centerline diverged as model angle of attack was increased. A photograph of the model installed on the High-Pitch support system is shown in Fig. 5.

2.4 INSTRUMENTATION AND TEST PROCEDURES

Model pressures were measured at 25 locations by individual transducers located inside the orbiter and the external tank. The locations of the pressure orifices are shown in Fig. 6 and are summarized as follows:

<u>Location</u>	<u>Number of Pressure Orifices</u>	<u>Size Transducer</u>
Orbiter base	9	± 2.5 psid
Body Flap Upper Surface	8	± 2.5 psid
OMS Pod	2	± 10 psid
AADS (ET)	2	± 10 psid
40-deg Cone (ET)	4	± 10 psid

All pressure transducers were referenced to tunnel plenum pressure.

In addition to the model pressures, forces and moments were measured by strain-gage balances as follows:

<u>Balance Location</u>	<u>Type</u>	<u>Model Forces and Moments Measured or Calculated</u>
Orbiter	6-component	Orbiter normal force, side force, axial force, pitching-moment, rolling moment, yawing moment
Wing	3-component	Wing normal force, bending moment, and torsional moment
Vertical Stabilizer	3-component	Vertical stabilizer side force, bending moment, and torsional moment
Inboard Elevon	1-component	Inboard elevon hinge moment
Outboard Elevon	1-component	Outboard elevon hinge moment
*Dual Stings	4-component (each)	Launch vehicle normal force, side force, and pitching moment

*Primary use of data from the gaged stings was to calculate deflections resulting from aerodynamic loading.

Sting pitch and roll angles were determined from the outputs of synchro-transmitters during tests conducted with the model supported on the sting support system. During the second test entry, sting pitch and roll angles were determined from the outputs of a synchro-transmitter and a potentiometer, respectively. The electrical signals from all position indicating devices, strain-gage balances, and pressure transducers were digitized for on-line data reduction and tabulation.

3.0 TEST DESCRIPTION

3.1 PROCEDURE

During both test entries, the desired tunnel conditions were set and, during the portion of the tests devoted to determination of test section flow angularities, model angle of attack was varied at zero sideslip angle ($\phi = 0$ and 180 deg), or model sideslip angle was varied at a nominal angle of attack of zero deg ($\phi = 90$ and -90 deg). During testing of the α/β matrix, orbiter sideslip was varied from -6 to 6 deg at nominal constant angles of attack of -8 to 8 deg.

3.2 DATA REDUCTION

All measured pressures were converted into coefficient form, and those located on the base of the orbiter were used to correct measured normal force, axial force, and pitching moment for base pressure force.

Force and moment coefficient data for the orbiter were computed in the body axis coordinate system using the projection of the orbiter nose on the longitudinal centerline of the external tank as the moment reference point. Forces and moments from the wing, vertical tail, and elevons were computed about moment reference points unique to the individual model components. The locations of the moment reference points and directions of positive forces and moments are shown in the sketches of Figs. 2 and 7.

Values of flow angularity in the pitch and sideslip planes determined during the first test entry (sting support system) along with the vertical location of the orbiter balance center relative to the tunnel centerline are presented in Fig. 8. The data presented in Fig. 8a represent selected pitch plane flow angularity values determined from various model component balances. The listing below identifies the balance outputs considered in the determination of pitch plane flow angularity (AFA) during the first test entry.

AFA (Sting Support System)						
M_{∞}	$\phi = 0, 180$			$\phi = -90, 90$		
	CNORB	CNSTING	CNW	CYORB	CYSTING	CSV
0.60	U	U	D	C	C	C
0.90	U	U	D	C	C	C
0.95	U	U	D	-	-	-
1.10	U	U	D	C	C	C
1.25	U	U	D	C	C	C
1.55	U	U	D	-	-	-

U = Utilized

C = Considered

D = Discarded

Wing balance data were discarded from consideration in the determination of AFA because of large zero shifts in that balance early in the testing period. Figure 8b presents various average values of AFA grouped as follows: all usable data (excepting wing data), data obtained at 0- and 180-deg roll, data obtained at ± 90 -deg roll, and depicted as a dashed line, the values selected by the investigator as the data correction, relying primarily on the values obtained at 0- and 180-deg roll.

Values of test section sideslip plane flow angularity, BFA, determined from the various balances during the first test entry are presented in Fig. 8c and the balances utilized are identified below:

M_∞	BFA (Sting Support System)				
	$\phi = -90, 90$			$\phi = 0, 180$	
	CNORB	CNSTING	CNW	CYORB	CSV
0.60	C	C	C	U	U
0.90	C	C	C	U	U
0.95	-	-	-	U	U
1.10	C	-	C	U	U
1.25	C	C	C	D	D
1.55	-	-	-	U	U

U = Utilized

C = Considered

D = Discarded

Except for the orbiter data at $M_\infty = 1.55$, $\phi = 0$ -and 180 -deg roll, all data indicated a flow from right to left when viewed looking upstream. Figure 8d presents average values of BFA determined at 180 -deg roll angle increments and the values selected as angle corrections. Values of BFA at $M_\infty = 1.25$ exhibited a departure from the trend established at other Mach numbers which is believed to be a result of some unknown flow field phenomena not necessarily associated with test section flow angularity. These values were therefore excluded from consideration in the determination of the flow field correction.

The location of the orbiter balance center (Fig. 8e) indicates a fairly small departure, as a function of pitch angle, from its location at $\alpha = 0$ deg. Although the sting support system will normally maintain a model close to the tunnel centerline as sting pitch is varied, this desirable feature was precluded by two geometric factors; (1) the orbiter balance was positioned (at zero deg roll) above the horizontal plane of the sting system, and (2) the sting pitch requirements of the test required a pitch center aft of the model.

Flow angularity values determined for the 0.03-scale launch vehicle during the second test entry (high-pitch support system) are presented in Fig. 9. As with the first test entry presentation, Fig. 9a depicts the pitch plane flow angularity values determined from the various force measuring devices at 180 -deg opposed roll orientations and the model component balance data utilized in the determination of the correction function are identified below.

AFA (High-Pitch Support System)

M_∞	$\phi = 0, 180$				$\phi = -90, 90$		
	CNORB	CNSTING	CNW	CBW	CYORB	CYSTING	CSV
0.60	D	U	D	U	U	U	U
0.90	D	U	D	U	U	U	U
1.10	D	D	D	-	-	-	-
1.25	D	D	D	U	U	U	U
1.55	D	U	D	U	-	-	-

U = Utilized

D = Discarded

All orbiter and wing normal force data were discarded from consideration as were sting data at $M_\infty = 1.10$ and 1.25 because of non-parallel, non-linear characteristics exhibited at 180-deg roll orientation only. Wing bending was however given consideration at 0- and 180-deg roll orientation because the two data sets were parallel. Side force measurements were utilized at all Mach numbers at which tests were conducted at -90 and 90-deg roll and therefore provided the primary source of AFA values. The average values of all data as well as the 180-deg roll opposed measurements and the selected angle corrections (dashed line) are shown in Fig. 9b. A third order polynomial function of Mach number was utilized to fit the correction although any lower order function would probably have described the correction equally as well.

Values of test section sideslip plane flow angularity, BFA, for the high-pitch model supported tests are presented in Figs. 9c and d and the balance components considered are identified below.

BFA (High-Pitch Support System)

M_∞	$\phi = -90, 90$			$\phi = 0, 180$		
	CNORB	CNSTING	CNW	CYORB	CYSTING	CSV
0.60	D	D	D	U	U	U
0.90	D	D	D	U	U	U
1.10	-	-	-	U	U	U
1.25	D	D	D	U	U	U
1.55	-	-	-	U	U	U

U = Utilized

D = Discarded

During the analysis of the normal force data obtained at -90 and 90-deg roll angles, it became evident that values of BFA determined from these balance components produced higher values of

flow angularity than did the sideforce indicating balance components at 0- and 180-deg roll angles. Since the orbiter and the orbiter wing were effectively shielded at -90 deg roll angle by the ET and the SRB's from any crossflow component approaching from right to left, it was concluded that values of BFA determined by the orbiter and wing balances were not representative of the flow angularity and were eliminated from consideration. Values of BFA were therefore, as in the case of the first entry data, determined from sideforce balance component data at model roll angles of 0 and 180 deg.

The vertical location of the orbiter balance as the high-pitch sting was pitched, Fig. 9e, shows the large excursion from the centerline experienced by the balance at $\phi = 180$ deg. The resultant proximity of the model to the tunnel floor could have produced the erroneous appearing normal-force data at 180-deg roll angle.

Following determination of the flow angularity corrections shown in Figs. 8b and d (sting support system), and Figs. 9b and d (high-pitch support system), the flow angularity correction functions indicated by the dashed lines were vectorially added to the uncorrected model attitudes during a post test data reduction.

3.3 UNCERTAINTY OF MEASUREMENTS

Uncertainties (bands which include 95 percent of the calibration data) of the basic tunnel parameters, shown in Fig. 10, were estimated from repeat calibrations of the instrumentation and from the repeatability and uniformity of the test section flow during tunnel calibration. Additional information concerning the uncertainties in the free-stream properties is discussed in Refs. 3 and 4. Uncertainties in the instrumentation systems were estimated from repeat calibrations of the systems against secondary standards whose uncertainties are traceable to the National Bureau of Standards calibration equipment. The instrument uncertainties are combined using the Taylor series method of error propagation described in Ref. 5 to determine the uncertainties of the reduced parameters shown below:

	1.55	-4/0	±0.0014	±0.0016	±0.0014
	↓	4/0	±0.0014	±0.0016	±0.0014

The uncertainties in model angle of attack and sideslip resulting from uncertainties in sting pitch, sting roll, and sting/balance deflections were estimated to be ± 0.10 deg. The uncertainty in the determination of flow angularity correction was estimated to be ± 0.10 deg. In combined form, the final uncertainties in model angle of attack and sideslip are estimated to be ± 0.14 deg.

Another, statistically oriented determination of the uncertainty associated with the flow angularity measurements is presented in the Appendix.

Pressure coefficient uncertainties for both model tests are estimated for typical test conditions and model attitudes as follows:

± 2.5 psid Transducer Range

<u>M_∞</u>	<u>CP</u>
0.60	± 0.0074
0.90	± 0.0041
0.95	± 0.0038
1.10	± 0.0033
1.15	± 0.0031
1.25	± 0.0029
1.55	± 0.0024

± 10.0 psid Transducer Range

<u>M_∞</u>	<u>CP</u>
0.60	± 0.0096
0.90	± 0.0071
0.95	± 0.0068
1.10	± 0.0062
1.15	± 0.0061
1.25	± 0.0059
1.55	± 0.0056

4.0 DATA PACKAGE PRESENTATION

A summary of test conditions is presented in Tables 1 and 2 correlating the type of data acquired with test Part Number, Mach number, Reynolds number, and model attitude schedule. A sample of the tabulated data is shown in Table 3. The nomenclature associated with the tabulation is given in Table 4.

A copy of all data, either in tabular form or as a micro-film record, and including both corrected (flow angularity included), and uncorrected model attitudes, was transmitted to the following organizations: (1) Rockwell International Space Division, Downey, California, (2) NASA-Johnson Space Center, Houston, Texas, and (3) Marshall Space Flight Center, Huntsville, Alabama. Magnetic tapes containing all data were transmitted to Chrysler Michoud Defense Space Division, New Orleans, Louisiana.

Elevon Coefficients

CHEI	Inboard elevon hinge moment coefficient, moment/ $Q(S_{REF})(l_{REF})$
CHEO	Outboard elevon hinge moment coefficient, moment/ $Q(S_{REF})(l_{REF})$

Sting Coefficients

CLM	Pitching-moment coefficient of the sting, moment/ $Q(S_{REF})L_{REF}$
CN	Normal force coefficient of the sting, force/ $Q(S_{REF})$
CY	Side force coefficient of the sting, force/ $Q(S_{REF})$

APPENDIX

UNCERTAINTY OF FLOW ANGULARITY MEASUREMENTS

R. E. Graham

Analysis and Evaluation Division (DOTA)
Arnold Engineering Development Center

An analysis of the overall uncertainty of the flow angle measurements has been made based upon selected results from the test. Those results selected as representative (see text for rationale) are presented in Table A-1 and were used in the present study.

A backward elimination regression analysis was done for the sting and high-pitch support systems AFA and BFA results using a cubic polynomial in M as the trial mathematical model. By this process, those terms of powers of M determined significant by the F test at the 95% confidence level were retained in the regression equation. It was determined that the sting support AFA and BFA were best represented as a cubic polynomial in M, that the high pitch AFA was linear with M and that the high pitch BFA was independent of M. The standard errors of estimate \hat{S} (at the mean) resulting are given in Table A-2.

It was determined by using the F statistic (formed from the ratio of variances) that at the 95% confidence level, the \hat{S} 's of the sting AFA, sting BFA and high-pitch AFA could be pooled to form a combined standard error $\hat{S}_{\text{pooled}} = 0.048$ deg

with a degrees of freedom $\nu_{\text{pooled}} = 48$. The pooled \hat{S} and the

high-pitch BFA were then combined using the root sum squared relationship yielding $\hat{S}_{\text{combined}} = 0.128$ deg with a combined

degrees of freedom $\nu_{\text{combined}} = 12$ (from the Welch-Satterthwaite

formula). The uncertainty of the flow angularity measurements at the 95% confidence level for the combined results $U_{95\%}$ was determined by the following relationship where $t_{\alpha/2, \nu_{\text{combined}}}$ represents the Student's t value at 0.025 and ν of 12

$$U_{95\%} = \pm (t_{\alpha/2, \nu_{\text{combined}}}) * \hat{S}_{\text{combined}}$$

$$U_{95\%} = \pm 0.279 \text{ deg.}$$
